# SOME REMARKS ON SET THEORY IV 

Paul Erdös

1. SOME PROBLEMS OF SIERPIŃSKI. Sierpiński [6], [7, pp. 9-11] proved that the continuum hypothesis is equivalent with the existence of a decomposition of the plane into two sets $S_{1}$ and $S_{2}$ such that $S_{1}$ is intersected by every horizontal line (and $\mathrm{S}_{2}$ by every vertical line) in at most a denumerable set. We begin with a generalization of this result.

THEOREM 1. Assume that $2^{{ }^{\circ} 0}=\aleph_{1}$. Decompose the set of all lines in the plane into two arbitrary disjoint sets $\mathrm{L}_{1}$ and $\mathrm{L}_{2}$. Then there exists a decomposition of the plane into two sets $\mathrm{S}_{1}$ and $\mathrm{S}_{2}$ such that each line of $\mathrm{L}_{\mathrm{i}}$ intersects $\mathrm{S}_{\mathrm{i}}(\mathrm{i}=1,2)$ in at most a denumerable set.

This theorem clearly strengthens one part of Sierpiński's result. To prove the theorem, let $\left\{1_{\alpha}\right\} \quad\left(\alpha<\Omega_{1}\right)$ be a well-ordering of the lines in the plane, and let $1_{1}$ belong to $L_{i}$. We begin the construction of the sets $S_{1}$ and $S_{2}$ by assigning all points of $1_{1}$ to $S_{3-\mathrm{i}}$. Suppose that for $\beta<\alpha$ the points of the lines $\mathrm{l}_{\beta}$ have been divided between $S_{1}$ and $S_{2}$, and that $l_{\alpha}$ belongs to $L_{i}$. Then we assign to $S_{3-i}$ all points of $1_{\alpha}$ which lie on none of the lines $1_{\beta}(\beta<\alpha)$. The sets $S_{1}$ and $S_{2}$, thus defined by transfinite induction, possess the required properties, since each ordinal less than $\Omega_{1}$ is denumerable.

If we do not appeal to the continuum hypothesis, our proof gives a decomposition of the plane into two sets $S_{i}(i=1,2)$ such that each line of $L_{i}$ intersects $S_{i}$ in a set of power less than $2^{* 0}$. (Compare Sierpiński's remark immediately after Theorem 4 on page 6 of [8].)

The other half of Sierpiński's theorem can also be strengthened. To this end, we want to find necessary and sufficient conditions on two disjoint sets of lines $L_{1}$ and $L_{2}$ such that the existence of a decomposition of the plane into two sets $S_{1}$ and $S_{2}$, with every line of $L_{i}$ intersecting $\mathrm{S}_{\mathrm{i}}(\mathrm{i}=1,2)$ in at most a denumerable set, implies the continuum hypothesis. Such conditions may be stated as follows: Both $L_{1}$ and $\mathrm{L}_{2}$ must contain nondenumerably many lines, and one of them, say $\mathrm{L}_{1}$, must contain $2^{{ }^{\kappa_{0}}}$ lines; moreover, there must not exist a point $p$ such that all but $\aleph_{1}$ lines of $L_{1}$ and all but $\mathcal{N}_{0}$ lines of $L_{2}$ pass through $p$.

We suppress the proof, since it is somewhat lengthy and contains no ideas which are not involved in Sierpiński's method [6, p. 2], [7, pp. 10, 11]. Just to give a hint to the reader, we remark that in the proof we distinguish two cases: in Case I, if T is any set of power $\boldsymbol{N}_{1}$, some line of $\mathrm{L}_{1}$ does not meet T ; in Case II, this condition is not satisfied.

Various problems arise in connection with Theorem 1. Sierpiński [9] proved that the continuum hypothesis is equivalent with the following statement: Threedimensional space $\mathrm{E}^{3}$ can be decomposed into three sets $\mathrm{S}_{\mathrm{i}}(\mathrm{i}=1,2,3)$ such that each line parallel to one of the axes $\mathrm{OX}_{\mathrm{i}}(\mathrm{i}=1,2,3)$ intersects $\mathrm{S}_{\mathrm{i}}$ in a finite set. This suggests several questions:
a) Distribute the lines in $\mathrm{E}^{3}$ into three arbitrary sets $\mathrm{L}_{\mathrm{i}}(\mathrm{i}=1,2,3)$. Does there exist a decomposition of $\mathrm{E}^{3}$ into three sets $\mathrm{S}_{\mathrm{i}}$ such that the intersection of each line of $L_{i}$ with the corresponding set $\mathrm{S}_{\mathrm{i}}$ is finite?
b) Does there exist a decomposition of the plane into three sets $\mathrm{S}_{\mathrm{i}}(\mathrm{i}=1,2,3)$ such that each horizontal (vertical, oblique) line intersects $S_{1}\left(S_{2}, S_{3}\right)$ in a finite set?
c) Does there exist a set of three directions $d_{i}(i=1,2,3)$ in the plane, together with a decomposition of the plane into three corresponding sets $S_{i}$, such that every line with the direction $d_{i}$ intersects $S_{i}$ in a finite set?

The three questions deal with progressively weaker conjectures; the last is due to Sierpiński. I do not know the answer to any of them.

Sierpiński's theorem at the beginning of this section can clearly be formulated in the following more general form. Let T be a set of power m . By $\mathrm{T}^{2}$ we denote the set of all pairs ( $\mathrm{a}, \mathrm{b}$ ) with $\mathrm{a} \in \mathrm{T}$ and $\mathrm{b} \in \mathrm{T}$. A horizontal line $l_{(a)}$ is defined as a set $\{(a, x)\}$, where $a \in T$ and $x$ runs through all elements of $T$; and a vertical line $l^{(b)}$ is defined as a set $\{(x, b)\}$, where $b \in T$ and $x$ runs through all elements of $T$. Then $T^{2}$ can be decomposed into two sets $S_{1}$ and $S_{2}$ such that $S_{1}$ is intersected by every horizontal line (and $S_{2}$ by every vertical line) in a set of power less than $m$. Now we prove the following result.

THEOREM 2. Let n be a cardinal number less than m , and let $\mathrm{T}^{2}=\mathrm{S}_{1} \cup \mathrm{~S}_{2}$, where $\mathrm{S}_{1}$ is intersected by every horizontal line in a set of power less than n . Then there exists a vertical line which intersects $S_{2}$ in a set of power $m$.

Theorem 2 is essentially due to Sierpiński [8, p. 6], though I am not sure that he ever stated it explicitly; for the sake of completeness I give a proof. Denote by $S_{a}$ the set of those $x$ for which the point ( $a, x$ ) lies in $l_{a} \cap S_{1}$. By assumption,
$\overline{\overline{\mathrm{S}_{\mathrm{a}}}}<\mathrm{n}<\mathrm{m}$. Thus by the lemma on page 55 of [2] there exists a subset $\mathrm{T}_{1}$ of T , of power $m$, such that the union of all sets $S_{a}\left(a \in T_{1}\right)$ is a proper subset of $T$; in other words, such that there exists an element b of T not contained in this union. But then clearly all the points ( $\mathrm{x}, \mathrm{b}$ ) with x in $\mathrm{T}_{1}$ are in $\mathrm{S}_{2}$; that is, the vertical line $1^{(b)}$ meets $S_{2}$ in a set of power $m$, as stated.

If we use the generalized continuum hypothesis, we can prove the following stronger result.

THEOREM 3. Let n be any cardinal number less than m. Let $\mathrm{T}^{2}=\mathrm{S}_{1} \cup \mathrm{~S}_{2}$, where $\mathrm{S}_{1}$ is intersected by every horizontal line in a set of power less than n . Then there exist two subsets $\mathrm{T}_{1}$ and $\mathrm{T}_{2}$ of T , each of power m , such that all points ( $\mathrm{a}, \mathrm{b}$ ) with a in $\mathrm{T}_{1}$ and b in $\mathrm{T}_{2}$ belong to $\mathrm{S}_{2}$.

By the lemma ${ }^{1}$ on page 56 of [2], there exist two sets $T_{1} \subset T$ and $T_{2} \subset T$, of power $m$, such that the set

$$
\mathrm{T}_{2} \cap\left(\bigcup_{\mathrm{a} \in \mathrm{~T}_{1}} \mathrm{~S}_{\mathrm{a}}\right)
$$

is empty. Thus all points $(\mathrm{a}, \mathrm{b})$ with a in $\mathrm{T}_{1}$ and b in $\mathrm{T}_{2}$ are in $\mathrm{S}_{2}$, as stated.
Sierpiński [8] proved that if $2^{N_{0}}=\aleph_{1}$, the plane is the union of countably many curves (here the word 'curve' is used to denote a point set $C$ for which there exists a direction such that every line in this direction intersects the set $C$ in at most one point). Earlier, Mazurkiewicz [5] had proved that the plane is not the union of

[^0]finitely many curves, and Sierpiński [8, p. 8] raised the question whether the continuum hypothesis is equivalent with the statement that the plane is the union of countably many curves.

The following theorem proves a conjecture of L. Patai, regarding the decomposition of the plane into countably many curves; I read the conjecture in a note book of Patai, after his death.

THEOREM 4. Assume that $2^{\kappa_{0}}=\aleph_{1}$. Let there be given a set of directions $\mathrm{d}_{\mathrm{n}}(\mathrm{n}=1,2, \cdots)$ in the plane such that, for every direction d in the plane, infinitely many of the $\mathrm{d}_{\mathrm{n}}$ are different from d . Then the plane is the union of countably many curves $\mathrm{C}_{\mathrm{n}}$ with the property that, for each $\mathrm{n}, \mathrm{C}_{\mathrm{n}}$ intersects every line parallel to $\mathrm{d}_{\mathrm{n}}$ in at most one point.

By hypothesis the set $\left\{\mathrm{d}_{\mathrm{n}}\right\}$ can be split into two infinite sets $\left\{\mathrm{d}_{\mathrm{i}}^{\prime}\right\}$ and $\left\{\mathrm{d}_{\mathrm{j}}^{\prime \prime}\right\}$ ( $\mathrm{i}, \mathrm{j}=1,2, \cdots$ ) such that no $d_{i}^{\prime}$ is parallel to any $d_{j}^{\prime \prime}$. By Theorem 1 the plane can be split into two sets $S_{1}$ and $S_{2}$ such that each line parallel to one of the $d_{i}^{\prime}$ ( $\mathrm{i}=1,2, \cdots$ ) intersects $\mathrm{S}_{1}$ in at most a countable set, and each line parallel to one of the $d_{j}^{\prime \prime}(j=1,2, \cdots)$ intersects $S_{2}$ in at most a countable set.

We will say that two points $u$ and $v$ of $S_{1}$ belong to the same class provided there exists a finite set of points $\left\{t_{1}, t_{2} \cdots, t_{k}\right\}$, with $t_{1}=u$ and $t_{k}=v$, such that each line $\left(t_{r}, t_{r+1}\right)(r=1,2, \cdots, k-1)$ is parallel to one of the directions $d_{i}^{\prime}$. The set $\mathrm{S}_{1}$ is thus partitioned into disjoint classes $\mathrm{B}_{\alpha}\left(1 \leq \alpha<\Omega_{1}\right)$; and since each line parallel to one of the $d_{i}^{\prime}$ intersects $S_{1}$ in at most a denumerable set, each class $B_{\alpha}$ is at most denumerable. We denote its points by $\mathrm{t}_{\alpha_{\mathrm{n}}}(\mathrm{n}=1,2, \cdots)$.

For $\mathrm{n}=1,2, \cdots$, let $\mathrm{C}_{\mathrm{n}}^{\prime}$ denote the set $\left\{\mathrm{t}_{\alpha \mathrm{n}}\right\} \quad\left(1 \leq \alpha<\Omega_{1}\right)$. Any two distinct points $\mathrm{t}_{\alpha_{1} \mathrm{n}}$ and $\mathrm{t}_{\alpha_{2} \mathrm{n}}$ in $\mathrm{C}_{\mathrm{n}}^{\prime}$ belong to two different classes; therefore the line joining them is not parallel to any of the $d_{i}^{\prime}(i=1,2, \cdots)$. It follows that $C_{n}^{\prime}$ is a curve which meets each line parallel to one of the $d_{i}^{\prime}$ in at most one point.

Similarly, the set $S_{2}$ can be decomposed into countably many curves $C_{n}^{\prime \prime}$, each of which meets each line parallel to one of the $\mathrm{d}_{\mathrm{j}}^{\prime \prime}$ in at most one point. This completes the proof of Theorem 4.

The condition that for every direction $d$ there exist infinitely many $d_{n}$ not parallel to $d$ can not be omitted from the hypothesis of Theorem 4. In fact, a simple modification of the proof of Mazurkiewicz [5] yields the following result: The plane is not the union of a finite number of curves $\mathrm{C}_{1}, \mathrm{C}_{2}, \cdots, \mathrm{C}_{\mathrm{n}}$ and a set S such that every line parallel to a certain direction d intersects $S$ in fewer than $2^{\kappa 0}$ points. We do not give the proof, since it is very similar to that of Mazurkiewicz.

The following question is now appropriate. Let the lines in the plane be divided into countably many disjoint classes $\mathrm{L}_{\mathrm{n}}(\mathrm{n}=1,2, \cdots)$. Can one then split the plane into countably many sets $\mathrm{S}_{\mathrm{n}}(\mathrm{n}=1,2, \cdots)$ such that each line of $\mathrm{L}_{\mathrm{n}}$ intersects $\mathrm{S}_{\mathrm{n}}$ in at most one point? I do not know the answer to this question. If it is in the affirmative, it clearly sharpens Theorem 4.
2. ON ADDITIVE NUMBER THEORY. Lorentz [3] recently proved the following conjecture of E. G. Straus and myself: Let $\left\{\mathrm{a}_{\mathrm{i}}\right\}_{1}^{\infty}$ be any increasing sequence of integers. Then there exists an increasing sequence $\left\{\mathrm{b}_{\mathrm{j}}\right\}$, of density 0 , such that every sufficiently large integer is of the form $\mathrm{a}_{\mathrm{i}}+\mathrm{b}_{\mathrm{j}}$. The following theorem shows that no analogous result holds for real numbers. In the statement of the theorem, the sum $A+B$ of two sets of numbers denotes the set of all numbers $a+b$ with $a$ in $A$ and b in B .

THEOREM 5. Assume the continuum hypothesis, and suppose that $\left\{\mathrm{S}_{\alpha}\right\}$ $\left(1 \leq \alpha<\Omega_{1}\right)$ is a family of $\aleph_{1}$ sets of real numbers, with the property that the set of all real numbers is not the union of countably many sets of the form $\mathrm{a}_{\mathrm{k}}+\mathrm{S}_{\alpha_{\mathrm{k}}}$
$(\mathrm{k}=1,2, \cdots)$. Then there exists a set A of power $\mathrm{N}_{1}$ such that none of the sets $\mathrm{A}+\mathrm{S}_{\alpha}\left(1 \leq \alpha<\Omega_{1}\right)$ is the set of all real numbers.

Before proving Theorem 5, we note that every family of $\aleph_{1}$ sets of measure zero (in particular, the family of sets of measure zero and type $G_{\delta}$ ) satisfies the hypothesis of the theorem; the same is true of every family of $\aleph_{1}$ sets of first category. I do not know whether the conclusion of the theorem holds whenever $\left\{\mathrm{S}_{\alpha}\right\}$ consists of $\aleph_{1}$ sets of measure zero and $\aleph_{1}$ sets of first category (since the union of two such sets can be the set of all real numbers, the hypothesis of Theorem 5 is here not satisfied).

We will now prove our theorem by constructing, by transfinite induction, two sequences of real numbers $\mathrm{y}_{\alpha}$ and $\mathrm{z}_{\alpha}\left(1 \leq \alpha<\Omega_{1}\right)$; the union of the elements of $\left\{\mathrm{y}_{\alpha}\right\}$ will serve as the set A ; and each set $\mathrm{A}+\mathrm{S}_{\alpha}$ will fail to contain the number $\mathrm{z}_{\alpha}$.

Suppose that, for $\gamma<\beta$, the numbers $\mathrm{y}_{\gamma}$ and $\mathrm{z}_{\gamma}$ have been chosen in such a way that, for every $\alpha<\beta$, each of the sets $\left\{\mathrm{y}_{\gamma}\right\}+\mathrm{S}_{\alpha}(\gamma<\beta)$ fails to contain $\mathrm{z}_{\alpha}$. By the hypothesis concerning the family $\left\{\mathrm{S}_{\alpha}\right\}$, the union $\cup\left(\mathrm{S}_{\beta}+\mathrm{y}_{\gamma}\right) \quad(\gamma<\beta)$ is not the set of real numbers; therefore we can choose a number $\mathrm{z}_{\beta}$ in the complement of this union. Also, the union $\cup\left[\mathrm{S}_{\alpha}+\left(-\mathrm{z}_{\alpha}\right)\right] \quad(\alpha \leq \beta)$ is not the set of real numbers (again, by the hypothesis in the theorem), and therefore we can chose $-\mathrm{y}_{\beta}$ in the complement of this union.

Thus the set $\mathrm{A}=\{\mathrm{y} \alpha\} \quad\left(1 \leq \alpha<\Omega_{1}\right)$ is defined by transfinite induction. Each $\mathrm{z}_{\alpha}$ is a member of none of the sets $\mathrm{S}_{\alpha}+\left\{\mathrm{y}_{\gamma}\right\} \quad(\gamma<\alpha)$, and of none of the sets $\mathrm{S}_{\alpha}+\left\{\mathrm{y}_{\beta}\right\}$ ( $\beta \geq \alpha$ ), and therefore the proof is complete.
3. ON A PROBLEM OF MARCZEWSKI. A countably additive measure $\mu \mathrm{de}$ fined in a space M is said to be separable if there exists in M a sequence of measurable sets $V_{n}$ with the property that, for each measurable set $E$ in $M$ and every $\eta>0$, there exists an index n such that

$$
\mu\left(\mathrm{V}_{\mathrm{n}}-\mathrm{E}\right)+\mu\left(\mathrm{E}-\mathrm{V}_{\mathrm{n}}\right)<\eta .
$$

A family F of sets is said to have the property (k) if each nondenumerable collection $\left\{\mathrm{S}_{\alpha}\right\}$ of sets in F contains a nondenumerable subcollection such that each pair of sets in this subcollection has a nonempty intersection.

Marczewski [4, pp. 129, 130] proved that if $\mu$ is a separable measure, then the family of sets of positive measure has the property (k), and he asked whether the theorem remains true when the condition of separability of $\mu$ is dropped. I will now show that, under a certain condition on $M$ and $\mu$, the answer is in the affirmative.

THEOREM 6. Let M be a set, and $\mu$ a measure defined on some subsets of M ; and let M be the union of countably many sets of finite measure. Then the family of sets of positive measure has the property ( $\mathbf{k}$ ).

It will clearly be sufficient to prove that if $\left\{\mathrm{S}_{\alpha}\right\} \quad\left(1 \leq \alpha<\Omega_{1}\right)$ is any family of distinct sets of positive measure, there exists a subfamily $\left\{\mathrm{S}_{\alpha_{\mathrm{k}}}\right\}\left(1 \leq \mathrm{k}<\Omega_{1}\right)$ such that $\mu\left(\mathrm{S}_{\alpha_{\mathrm{k}^{\prime}}}-\mathrm{S}_{\alpha_{\mathrm{k}^{\prime \prime}}}\right)>0$ for each pair of ordinals $\mathrm{k}^{\prime}$ and $\mathrm{k}^{\prime \prime}$ less than $\Omega_{1}$.

Let $M=\cup_{1}^{\infty} T_{n}$, where each $T_{n}$ is a set of finite positive measure, with $T_{n} \neq T_{m}$ for $\mathrm{n} \neq \mathrm{m}$. For at least one n there exist $\boldsymbol{\aleph}_{1}$ sets $\mathrm{S}_{\alpha}$ whose intersections with $\mathrm{T}_{\mathrm{n}}$ have positive measure; in fact, there exists a collection of $\boldsymbol{N}_{1}$ distinct sets $\mathrm{S}_{\alpha}$ for which $\mu\left(\mathrm{T}_{\mathrm{n}} \cap \mathrm{S}_{\alpha}\right)>\varepsilon$, where $\varepsilon$ is some positive constant. We denote these sets by $\mathrm{S}_{\alpha^{*}}$, and with the collection $\left\{\mathrm{S}_{\alpha^{*}}\right\}$ we associate an abstract graph G as follows: with each $\mathrm{S}_{\alpha^{*}}$ we associate an (abstract) vertex $\mathrm{p}_{\alpha}$; two vertices $\mathrm{p}_{\alpha^{\prime}}$ and $\mathrm{p}_{\alpha^{\prime \prime}}$ are connected by an edge if and only if $\mu\left(\mathrm{S}_{\alpha_{1}^{*}} \cap \mathrm{~S}_{\alpha \text { 数 }}{ }^{*}\right)>0$. A simple argument shows that among any $r$ vertices $p_{\alpha_{i}}(i=1,2, \cdots, r)$ with

$$
\mathbf{r}>\mu\left(\mathrm{T}_{\mathrm{n}}\right) / \varepsilon \quad\left(\mu\left(\mathrm{T}_{\mathrm{n}} \cap \mathrm{~S}_{\alpha^{*}}\right)>\varepsilon\right),
$$

at least two are connected by an edge. By a result of Dushnik and Miller [1, Theorem 5.22], there exists a set of $\aleph_{1}$ vertices $\mathrm{p}_{\alpha_{\mathrm{k}}}\left(1 \leq \mathrm{k}<\Omega_{1}\right)$ any two of which are connected by an edge; in other words, for any pair $\mathrm{k}^{\prime}$ and $\mathrm{k} "$ of ordinals less than $\Omega_{1}$, $\mu\left(\mathrm{S}_{\left.\alpha_{\mathrm{k}^{\prime}} \cap \mathrm{S}_{\alpha_{\mathrm{k} \mid}}\right)>0 \text {. This proves the theorem. }}^{\text {. }}\right.$

One final problem: Does there exist a family of $2^{N_{0}}$ sets of real numbers, each of positive measure, such that the intersection of any $\boldsymbol{\aleph}_{1}$ of them is empty? If $2^{\kappa_{0}}=\boldsymbol{\aleph}_{1}$, it is quite easy to show this.
